Build_train_NN_MNIST_part1

October 15, 2022

[1]:
```
# We will start by having only the input layer and a last classification layer.
```

[2]:
```
# Step 1. Import Tensorflow and other helper libraries

# make sure tensorflow is installed; uncomment the line before if you need to
# pip install tensorflow

# TensorFlow and tf.keras
import tensorflow as tf

# Helper libraries
import numpy as np
import matplotlib.pyplot as plt
```

The MNIST database (Modified National Institute of Standards and Technology database) is a large database of handwritten digits that is commonly used for training various image processing systems.

[3]:
```
# Step 2: load the MNIST data and convert pixel intensities to doubles
# Explore the shape of the data
mnist = tf.keras.datasets.mnist

(x_train, y_train), (x_test, y_test) = mnist.load_data()
x_train, x_test = x_train / 255.0, x_test / 255.0
print(x_train.shape)
print(x_test.shape)
```

```

```
# A Sequential model is appropriate for a plain stack of
# layers where each layer has exactly one input tensor and one output tensor.
# A Sequential model is not appropriate when:
#  - Your model has multiple inputs or multiple outputs
#  - Any of your layers has multiple inputs or multiple outputs
```

```
#  - You need to do layer sharing
#  - You want non-linear topology (e.g. a residual connection, a multi-branch␣
 ↪model)
```

[4]:
```
# Step 3: Build the tf.keras.Sequential model by stacking the following two␣
 ↪layers:

# A. The first layer in the neural network takes input signals(values) and␣
 ↪passes
# them on to the next layer. It doesn't apply any operations on the input␣
 ↪signals(values)
# and has no weights and biases values associated. In our network the input␣
 ↪signals
# are of size 28 by 28
# The first layer is of type "Flatten" and you can use an optional input shape
# (the input images are 28 by 28)
# Flattening is converting the data into a 1-dimensional array for input
# into to the next layer.

# B. The second layer is Dense (fully connected layer), the output shape is 1 x␣
 ↪10
# The size of the output is 10 because we have 10 possible characters: 0,1,2,..
 ↪,9

# Insert your code below:

model = tf.keras.models.Sequential([
    tf.keras.layers.Flatten(input_shape=(28,28)),
    tf.keras.layers.Dense(10),
])
```

[5]:
```
# Once a model is "built", you can call its summary() method to display its␣
 ↪contents:

model.summary()
```

```
Model: "sequential"
_________________________________________________________________
Layer (type)                 Output Shape              Param #
=================================================================
flatten (Flatten)            (None, 784)               0
_________________________________________________________________
dense (Dense)                (None, 10)                7850
=================================================================
Total params: 7,850
Trainable params: 7,850
Non-trainable params: 0
```

---

[6]:
```
# For each example the model returns a vector of "logits" or "log-odds" scores, one for each class.
# pass 1 training data image to the model and convert the predictions into a numpy array
predictions = model(x_train[:1]).numpy()
predictions
```

```
WARNING:tensorflow:Layer flatten is casting an input tensor from dtype float64
to the layer's dtype of float32, which is new behavior in TensorFlow 2.  The
layer has dtype float32 because it's dtype defaults to floatx.

If you intended to run this layer in float32, you can safely ignore this
warning. If in doubt, this warning is likely only an issue if you are porting a
TensorFlow 1.X model to TensorFlow 2.

To change all layers to have dtype float64 by default, call
`tf.keras.backend.set_floatx('float64')`. To change just this layer, pass
dtype='float64' to the layer constructor. If you are the author of this layer,
you can disable autocasting by passing autocast=False to the base Layer
constructor.
```

        0.04829573, 0.05542297, 0.03791475, 0.1855594 , 0.0472821 ]],
      dtype=float32)
```

[9]:
```
# Choose an optimizer and loss function for training

# Deep learning neural networks are trained using the stochastic gradient descent optimization
# algorithm. As part of the optimization algorithm, the error for the current state of the
# model must be estimated repeatedly. This requires the choice of an error function,
# conventionally called a loss function, that can be used to estimate the loss of the model so
# that the weights can be updated to reduce the loss on the next evaluation.
```

```
# The losses.SparseCategoricalCrossentropy loss takes a vector of logits and a␣
 ↪True index and
# returns a scalar loss for each example.

loss_fn = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)

# This loss is equal to the negative log probability of the true class: It is␣
 ↪zero if the model
# is sure of the correct class. This untrained model gives probabilities close␣
 ↪to random
# (1/10 for each class), so the initial loss should be close to -tf.math.log(1/
 ↪10) ~= 2.3.

loss_fn(y_train[:1], predictions).numpy()
```
